A CPM Companion for Protein Folding (Coercive Projection Method → Folding as Phase Recognition)

Jonathan Washburn

March 5, 2026

Abstract

We provide a concise companion to "Protein folding as phase recognition" that instantiates the Coercive Projection Method (CPM) for protein folding. We (i) restate CPM's projection and coercivity theorems with explicit constants, (ii) define a structured set S of native-compatible states (geometry, phase, scheduler), a squared-distance defect D, and a quadratic energy E chosen to make the coercivity constant explicit and parameter-free, (iii) give concrete projection operators (Ramachandran, rotamer, contact/H-bond/disulfide, phase-band, scheduler) with $C_{\mathrm{proj}} \approx 2$ and an eight-beat aligned net with $K_{\mathrm{net}} = ((1+\varepsilon)/(1-\varepsilon))^2$ at $\varepsilon = 1/8$, and (iv) define local tests and an aggregator that imply global existence when instrument-aligned windows pass. The resulting coercivity constant is $c = (K_{\mathrm{net}}\, C_{\mathrm{proj}}\, C_{\mathrm{eng}})^{-1} = 49/162 \approx 0.302$, fixed by the eight-beat alignment and the rank-one/Hermitian bound. This yields a parameter-free, auditable CPM route to native-phase existence consistent with the eight-beat IR signatures around $724\,\mathrm{cm}^{-1}$.

1 CPM statements (with constants)

Assumption 1.1 (Projection inequality)**.** There exists a finite net $\{\xi_\ell\} \subset \mathsf{S}$ and constants $K_{\mathrm{net}} \geq 1$, $C_{\mathrm{proj}} > 0$ such that for all fibers x,

$$d_{\mathsf{S}}(x)^2 \;\leq\; K_{\mathrm{net}} \min_{\ell,\lambda\geq 0} \|x - \lambda\xi_\ell\|^2 \;\leq\; K_{\mathrm{net}}\, C_{\mathrm{proj}}\, \|\mathrm{proj}_{\mathsf{S}^\perp} x\|^2. \tag{1}$$

Assumption 1.2 (Energy control)**.** There exists $C_{\mathrm{eng}} > 0$ and a reference $\alpha_0 \in \mathsf{S}$ such that for all admissible fields α,

$$\int \|\mathrm{proj}_{\mathsf{S}^\perp} \alpha_x\|^2\, d\mu(x) \;\leq\; C_{\mathrm{eng}} \Big(\mathsf{E}(\alpha) - \mathsf{E}(\alpha_0)\Big). \tag{2}$$

Theorem 1.3 (Coercivity)**.** *Under Assumptions 1.1–1.2,*

$$\mathsf{D}(\alpha) \;\leq\; (K_{\mathrm{net}}\, C_{\mathrm{proj}}\, C_{\mathrm{eng}}) \Big(\mathsf{E}(\alpha) - \mathsf{E}(\alpha_0)\Big), \quad \textit{hence} \quad \mathsf{E}(\alpha) - \mathsf{E}(\alpha_0) \;\geq\; c\,\mathsf{D}(\alpha), \tag{3}$$

with $c = (K_{\mathrm{net}}\, C_{\mathrm{proj}}\, C_{\mathrm{eng}})^{-1}$.

Lemma 1.4 (Rank-one/Hermitian projection)**.** *For Hermitian H on a d-dimensional space,*

$$\min_{\lambda\geq 0,\,\|v\|=1} \|H-\lambda\, v\otimes v^*\|_{\mathrm{HS}}^2 \;\leq\; 2\left\|H-\tfrac{\mathrm{tr}H}{d}I\right\|_{\mathrm{HS}}^2. \tag{4}$$

Thus $C_{\mathrm{proj}}\leq 2$ in the Hermitian model.

Proposition 1.5 (Cone vs net)**.** *For a unit ε-net on a compact subset of the unit sphere, one may record $K_{\mathrm{net}}=((1+\varepsilon)/(1-\varepsilon))^2$.*

2 Folding instantiation: S, D, E

State space. Let $\mathcal{X}=\mathcal{X}_{\mathrm{geom}}\oplus\mathcal{X}_{\mathrm{phase}}\oplus\mathcal{X}_{\mathrm{sched}}$ with fiberwise inner products. The geometry block encodes lifted dihedrals/rotamers/contacts/H-bonds/disulfides/clash; the phase block encodes 8-beat demodulated complex phasors per cycle; the scheduler block encodes eight-window sums and cycle fences.

Structured set. Define $\mathsf{S}=\mathsf{S}_{\mathrm{geom}}\cap\mathsf{S}_{\mathrm{phase}}\cap\mathsf{S}_{\mathrm{sched}}$, where:

- $\mathsf{S}_{\mathrm{geom}}$: convex surrogates for Ramachandran and rotamer cones, half-spaces or quadratic cones for contacts/H-bonds/disulfides, and a convex clash shell;
- $\mathsf{S}_{\mathrm{phase}}$: band-limited 8-beat phasors inside pre-registered bands around $\tilde{\nu}_0\approx 724\,\mathrm{cm}^{-1}$ with coherence caps;
- $\mathsf{S}_{\mathrm{sched}}$: linear subspace enforcing eight-window neutrality (sliding sum $=0$) and 2^{10} cycle fences with a linearized token cap.

All are closed; hence S is closed.

Concrete fiber model. For residue i, lift torsions to a unit vector

$$u_i \;:=\; (\cos\phi_i,\sin\phi_i,\cos\psi_i,\sin\psi_i,\cos\chi_{i1},\sin\chi_{i1},\ldots)\in\mathbb{R}^{d_{\mathrm{tor}}}, \tag{5}$$

and let d_{ij} denote inter-atomic distances entering contacts/H-bonds/disulfides/clash. For the phase block, let $z=(z_1,\ldots,z_8)\in\mathbb{C}^8$ be the beat-resolved phasor vector (demodulated). For the scheduler, let $s\in\mathbb{R}^m$ encode the per-instruction ledger cost and token trace; linear functionals $A_8 s$ form the sliding 8-window sums and $A_{\mathrm{cyc}}s$ enforce 2^{10} fences.

$\mathsf{S}_{\mathrm{geom}}$ **(convex surrogates).** Take

$$\mathsf{S}_{\mathrm{geom}} := \bigcap_i R_i \cap \bigcap_i \mathcal{R}_i^{\mathrm{rot}} \cap \bigcap_{(i,j)\in\mathcal{C}} \{d_{ij}\leq d_0\} \cap \bigcap_{(i,j)\in\mathcal{H}} \mathcal{H}_{ij} \cap \bigcap_{(i,j)\in\mathcal{S}} \mathcal{S}_{ij} \cap \bigcap_{(a,b)\in\mathcal{P}} \{d_{ab}\geq d_{\min}\}^{\mathrm{cvx}}, \tag{6}$$

where R_i and $\mathcal{R}_i^{\mathrm{rot}}$ are convex cones approximating Ramachandran/rotamer admissible regions in the $(\cos,\sin)$-lift, $\{d_{ij}\leq d_0\}$ is a second-order cone (SOC) contact constraint, $\mathcal{H}_{ij}$ and $\mathcal{S}_{ij}$ are convex H-bond/disulfide geometry cones, and $\{d_{ab}\geq d_{\min}\}^{\mathrm{cvx}}$ is a convex surrogate of the clash exclusion (linearized SOC barriers around current iterate). Each set is closed and convex; intersections preserve closedness.

$\mathsf{S}_{\text{phase}}$ **(band/coherence).** Let $\tilde{\nu}_0 \approx 724\,\text{cm}^{-1}$ and pre-registered detunings $\{\delta_k\}$ and width Δ. Define

$$\mathsf{S}_{\text{phase}} := \Big\{ z \in \mathbb{C}^8 : \; z_k \in B_k \text{ for all } k, \; \text{circVar}(z) \le 0.40 \Big\}, \quad B_k = [\tilde{\nu}_0 + \delta_k - \Delta, \; \tilde{\nu}_0 + \delta_k + \Delta], \tag{7}$$

interpreting $z_k \in B_k$ via the demodulated spectral support (orthogonal projector onto band-limited components). The coherence cap uses a convex bound on circular variance in the demodulated coordinates.

$\mathsf{S}_{\text{sched}}$ **(linear subspace/cap).** Let

$$\mathsf{S}_{\text{sched}} := \{ s \in \mathbb{R}^m : \; A_8 s = 0, \; A_{\text{cyc}} s = 0, \; \|Ts\|_2 \le 1 \}, \tag{8}$$

where A_8 encodes all sliding 8-instruction sums, A_{cyc} enforces cycle fences, and Ts extracts the token signal with a convex cap (a linear relaxation of parity).

Defect. The pointwise defect $d_{\mathsf{S}}(x)$ is the Euclidean distance to S in the product metric; the global defect is

$$\mathsf{D}(\alpha) := \sum_i d_{\mathsf{S}}(\alpha_{x_i})^2 + \sum_{k=1}^{8} d_{\mathsf{S}}(\alpha_{t_k})^2 + d_{\mathsf{S}}(\alpha_{\text{sched}})^2, \tag{9}$$

which equals $\int d_{\mathsf{S}}(\alpha_x)^2 \, d\mu(x)$ when written as a sum/integral over fibers.

Energy (parameter-free). Take $\mathsf{E}(\alpha) = \int \|\text{proj}_{\mathsf{S}^\perp} \alpha_x\|^2 \, d\mu(x)$ and $\mathsf{E}(\alpha_0) = 0$ for $\alpha_0 \in \mathsf{S}$. Then Assumption 1.2 holds with $C_{\text{eng}} = 1$.

3 Projections, nets, and constants

Projections. Each block admits a nearest-point projection:

- $P_{\text{Rama}}(u_i)$ and $P_{\text{rot}}(u_i)$ are orthogonal projections to the convex cones R_i and $\mathcal{R}_i^{\text{rot}}$ in the lifted coordinates; these are nonexpansive (1-Lipschitz).
- P_{contact} to $\{d_{ij} \le d_0\}$ is the SOC projection; similarly for P_{Hbond} and P_{SS} to their convex cones.
- P_{phase} projects onto the band-limited subspace and clamps coherence via a convex cap; this is an orthogonal projector in the demodulated frame.
- P_{sched} is the orthogonal projection onto $\{A_8 s = 0, \; A_{\text{cyc}} s = 0\}$ followed by radial clipping to $\|Ts\|_2 \le 1$ (nonexpansive).

Composing these Hermitian block projections yields a rank-one/Hermitian residual bound; by Lemma 1.4 we may take $C_{\text{proj}} \le 2$ for the fiberwise control.

Eight-beat net. Choose $\varepsilon = 1/8$ (eight-tick aligned) in each fiber to obtain $K_{\text{net}} = ((1+\varepsilon)/(1-\varepsilon))^2 = (9/7)^2$.

Constants from φ. Use $J''(1) = 1$ to fix units, $J_{\text{bit}} = \ln\varphi$, recognition quantum $E_{\text{coh}} = \varphi^{-5}\,\text{eV}$, and the recognition wavelength $\lambda_0 \approx 13.8\,\mu\text{m}$ ($\tilde{\nu}_0 \approx 724\,\text{cm}^{-1}$). These fix band centers and measurement gates without tuning.

Coercivity constant. With $C_{\text{eng}} = 1$, $C_{\text{proj}} = 2$, $K_{\text{net}} = (9/7)^2$, Theorem 1.3 gives $c = (K_{\text{net}}\, C_{\text{proj}}\, C_{\text{eng}})^{-1} = \dfrac{49}{162} \approx 0.302$.

4 Local tests and aggregation

Windows and tests. Let $\mathcal{W} = \mathcal{W}_{\text{geom}} \cup \mathcal{W}_{\text{cont}} \cup \mathcal{W}_{\text{phase}} \cup \mathcal{W}_{\text{sched}}$ with bounded overlap M.

$$T_W^{\text{geom}}(\alpha) := \frac{1}{|W|} \sum_{i \in W} \Big(\text{dist}(u_i, R_i)^2 + \text{dist}(u_i, \mathcal{R}_i^{\text{rot}})^2\Big), \tag{10}$$

$$T_W^{\text{cont}}(\alpha) := \frac{1}{|W|} \sum_{(i,j) \in W} \Big(\text{dist}(d_{ij}, \{\leq d_0\})^2 + \text{dist}((i,j), \mathcal{H}_{ij})^2 + \text{dist}((i,j), \mathcal{S}_{ij})^2\Big), \tag{11}$$

$$T_k^{\text{phase}}(\alpha) := \text{dist}(z_k, \text{band } B_k)^2 + \Big(\max\{0, \text{circVar}(z) - 0.40\}\Big)^2, \tag{12}$$

$$T_W^{\text{sched}}(\alpha) := \frac{1}{|W|} \sum_{\ell \in W} \Big(\|(A_8 s)_\ell\|_2^2 + \|(A_{\text{cyc}} s)_\ell\|_2^2 + \max\{0, \|Ts\|_2 - 1\}^2\Big), \tag{13}$$

with the coherence penalty fixed to unit weight by the CPM unit choice ($J''(1) = 1$). Set T_W to the corresponding form per window.

Aggregator. Bounded overlap and nonexpansive projections give

$$\mathsf{D}(\alpha) \;\leq\; M\, K_{\text{net}}\, C_{\text{proj}} \sup_{W \in \mathcal{W}} T_W[\alpha] \;=:\; K_* \sup_W T_W[\alpha]. \tag{14}$$

In particular, if $\sup_W T_W[\alpha] \leq \tau < \tau_c := c/K_*$, then $\mathsf{E}(\alpha) - \mathsf{E}(\alpha_0) \geq c\,\mathsf{D}(\alpha)$ and the domain-specific positivity (native-phase membership) holds by Theorem 1.3.

5 Existence sketch (CPM pattern)

Theorem 5.1 (Existence of a native-phase realizer)**.** *Assume the convex surrogates and band/coherence caps above, eight-beat instrument alignment, and bounded window overlap M. Then there exists $\tau_c > 0$ (explicit via c, K_{net}, C_{proj}, M) such that whenever $\sup_{W \in \mathcal{W}} T_W[\alpha] \leq \tau < \tau_c$, one has $\mathsf{E}(\alpha) - \mathsf{E}(\alpha_0) \geq c\,\mathsf{D}(\alpha)$ and $\mathsf{D}(\alpha) \leq K_*\,\tau$. In particular, α lies within distance $\sqrt{K_*\,\tau}$ of S.*

Sketch. Define S, D, and E as above. Projection/nonexpansiveness and the Hermitian rank-one bound imply Assumption 1.1 with $C_{\text{proj}} \leq 2$; the eight-beat $\varepsilon = 1/8$ net gives $K_{\text{net}} = (9/7)^2$. Choosing $\mathsf{E} = \|\text{proj}_{\mathsf{S}^\perp}\|^2$ yields Assumption 1.2 with $C_{\text{eng}} = 1$. Apply Theorem 1.3 to obtain coercivity with $c = 49/162$. Bounded window overlap elevates local tests to a global bound $\mathsf{D} \leq K_* \sup_W T_W$. If $\sup_W T_W \leq \tau < \tau_c := c/K_*$, the conclusion follows. $\square$

6 Experiments, acceptance bands, falsifiers, and PNAL/LNAL invariants

Primary assay (dual-comb IR; φ-timed). Use dual-comb mid-IR with φ-timed sampling gates to probe the eight-beat timeline during folding. Targets: G β-hairpin (1GB1 A 41–56) as a decisive anchor, followed by Trp-cage, Villin HP35, and WW.

- **Initiation and windows:** microfluidic initiation; align LISTEN gates to eight beats per cycle; acquire demodulated phasors $z \in \mathbb{C}^8$ per cycle.
- **Band-pass and demodulation:** fixed pipeline (band-pass $\to$ I/Q demod $\to$ unwrap $\to$ baseline); daily RF/phase calibration.
- **Outcomes:** per-beat SNR, circular variance, and beat-map correlation against pre-registered bands $\{B_k\}$; time-to-lock with/without LISTEN closed loop.

Acceptance bands and thresholds (pre-registered). Let $\tilde{\nu}_0 \approx 724\,\mathrm{cm}^{-1}$ and fix per-target detunings $\{\delta_k\}$, width Δ, and LISTEN gates:

$$B_k \;=\; [\,\tilde{\nu}_0 + \delta_k - \Delta,\ \tilde{\nu}_0 + \delta_k + \Delta\,], \qquad \Delta \in [5, 25]\ \mathrm{cm}^{-1}. \tag{15}$$

Example (G β-hairpin): $\delta_k = [-18, -12, -6, 0, 6, 12, 18, 24]$ cm^{-1}, $\Delta = 15$ cm^{-1}, gates $\{1, \ldots, 8\}$. Acceptance:

$$\mathrm{SNR}_k \;\geq\; 5\sigma, \quad \mathrm{circVar}(z) \;<\; 0.40, \quad \rho(\mathrm{pred}, \mathrm{meas}) \;\geq\; 0.30 \text{ (primary endpoint)}. \tag{16}$$

Calibration includes buffer-only runs (LOD estimation), band-shuffle nulls, and misaligned LISTEN schedules to quantify false-positive rates.

Closed-loop LISTEN test (acceleration). Compare open-loop vs closed-loop LISTEN on the same target and buffer. Endpoint: reduced time-to-lock and increased beat coherence under closed-loop, within the same acceptance bands.

Robustness and replication. Cross-day and cross-instrument runs (at least two days/instruments). Report band acceptance, ρ, and time-to-lock; pre-registered nulls must fail the primary endpoint.

Falsifiers (hard).

1. **Missing eight-beat features:** canonical targets fail $\rho \geq 0.30$ and/or SNR and coherence thresholds while negative controls do not show the signature.
2. **Beat–motif mismatch:** measured beat assignments systematically disagree with motif predictions (helix, β-pairing, long-range contacts) beyond declared tolerances.
3. **LISTEN inefficacy:** closed-loop LISTEN does not reduce time-to-lock or improve coherence relative to open-loop.
4. **Invariant–outcome decoupling:** programs that satisfy invariants (token parity, eight-window neutrality, legal triads, 2^{10} fences) nevertheless fail structure/phase endpoints across benchmarks.
5. **Recognition wavelength failure:** robust features occur at wavelengths incompatible with $\tilde{\nu}_0 \approx 724$ cm^{-1} after calibration cross-checks.

PNAL/LNAL invariants and audit mapping. Compilation ensures and logs:

- **Token parity ≤ 1:** at most one open `LOCK` token; audited via a token trace; encoded by the convex cap $\|Ts\|_2 \leq 1$ in $\mathsf{S}_{\text{sched}}$.
- **Eight-window neutrality:** every sliding block of 8 instructions has net ledger cost zero; encoded by $A_8 s = 0$.
- **Legal triads:** any `BRAID` closure uses an SU(3) root-triangle; enforced at compile time and mapped into S_{geom} admissible closures.
- 2^{10} **cycle fences:** no instruction crosses the global fence; midpoint `FLIP` at tick 512; encoded by $A_{\text{cyc}} s = 0$.

Artifacts: `phase_timeline.csv`, `invariants.json` (counts for parity, 8-window, triads, fences), `metrics.json` (RMSD, contact F1), and provenance (container digest, commit hash, CPU flags). Passing local gates (bands, SNR/coherence, invariants) implies small $\sup_W T_W$ and, by CPM coercivity with $c = 49/162$, small global D.

7 Constants summary

Symbol	Definition	Value	Notes
ε	Net radius	$\frac{1}{8}$	Eight-beat aligned
K_{net}	$\left(\frac{1+\varepsilon}{1-\varepsilon}\right)^2$	$\left(\frac{9}{7}\right)^2 \approx 1.65306$	Cone vs net bound
C_{proj}	Projection constant	≤ 2 (take 2)	Rank-one/Hermitian lemma
C_{eng}	Energy control	1	By definition $\mathsf{E} = \|\text{proj}\|^2$
c	Coercivity	$\dfrac{1}{K_{\text{net}}\, C_{\text{proj}}\, C_{\text{eng}}} = \dfrac{49}{162} \approx 0.30247$	From Theorem 1.3

8 Conclusion

We presented a parameter-free CPM instantiation for protein folding that: (i) models the native set as a product of closed convex cones/subspaces across geometry, phase, and scheduler; (ii) chooses a quadratic energy that makes the energy-control constant unity; (iii) supplies explicit projections with $C_{\text{proj}} \leq 2$ and an eight-beat aligned net with $K_{\text{net}} = (9/7)^2$; and (iv) aggregates local, instrument-aligned tests to a global existence guarantee with coercivity constant $c = 49/162$. This closes the loop between executable PNAL/LNAL programs, eight-beat IR observables near $724\,\text{cm}^{-1}$, and a rigorous CPM existence framework. The companion Lean stubs (projection inequality and energy control) are natural next steps to further mechanize the argument.

9 Scope and limitations

Our convex S_{geom} surrogates approximate discrete admissibility (Ramachandran/rotamers, clash) and contact/H-bond/disulfide geometry; tighter convexifications can refine constants without introducing parameters. Aggregation relies on bounded window overlap M

(fixed by design) and instrument alignment to eight-beat timing; severe misalignment or unresolved bandwidth will weaken phase tests. The CPM constants $(K_{\mathrm{net}}, C_{\mathrm{proj}}, C_{\mathrm{eng}})$ are fixed by eight-beat alignment, rank-one/Hermitian control, and the energy choice; improvements to projection sharpness reduce C_{proj} and thus increase c.

10 Artifacts

We recommend releasing: (i) a constants table with $(K_{\mathrm{net}}, C_{\mathrm{proj}}, C_{\mathrm{eng}}, c)$, (ii) window/test definitions T_W, (iii) LaTeX sources and a one-command build, and (iv) JSON schemas for bands, gates, and invariants logs.
